Report

1. UNSW Lower Campus

1.1 Datasets

Data	Size	#Voxels	Description
dtmbot.xyz	9.22 GB	641,624,355	A terrain with holes, in which the buildings fit
			· ·
tree.xyz	906 MB	59,640,000	Tree in lower campus
bld1-54.xyz	3.52GB	241,613,693 in total and	52 buildings in lower campus
(except for 26 and		4,646,418 per building	
46)		,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,	
be.xyz	249 MB	17,460,029	Built Environment (H13)
blockhouse.xyz	45.4 MB	3,392,202	Blockhouse (G6)
dalton.xyz	25.5 MB	1,887,512	Dalton (F12)
quadrangle.xyz	43.9MB	3,161,733	Quadrangle (E15)
roundhouse.xyz	79.9MB	6,037,174	Roundhouse (E6)
scithe.xyz	17.2MB	1,231,821	Science Theatre (F13)

Note that:

- For GIS-based voxels, its resolution is 20cm. All voxels are recorded in same INTEGER coordinate with offset (336000, 6245250, 20).
- For BIM-based voxels, its resolution is 10 cm. Each building is in its own INTEGER coordinate with MINXYZ.
 - o For be.xyz, the offset is (336300, 6245507, 25).
 - o For blockhouse.xyz, the offset is (336042, 6245613, 27).
 - o For dalton.xyz, the offset is (336305, 6245569, 29).
 - o For quadrangle.xyz, the offset is (336409, 6245580, 31).
 - o For roundhouse.xyz, the offset is (336047, 6245651, 25).
 - o For scithe.xyz, the offset is (336325, 6245582, 28).
- For the time being, we have already transferred INTEGER coordinates into NUMERIC coordinates (i.e., real geographical coordinates in CRS EPSG 28356).

1.2 Database Schema

Figure 1. Conceptual Model

Two Semantic Tables for IFC and class info:

Table		Columns		Description				
ifcc	ifcclass			ifcid, name		26 IFC class with corresponding name		
	4	ifcid [PK] i	integer		name charac	eter varying (50)	ø	
	1			1	IfcBea	m		
	2		2		IfcBuil	dingElementPart		
	3			3	IfcBuildingElementProxy			
obje	objclass			clas	ssid, name	classid 1-54 (exc 46) are building classid 55 is tree classid 56 is dtm	ID. e ID.	
		4	class [PK] i	id nteger	Ø*	name character varying (50)	
		1			55	tree		
		2			56	dtmbot		

3. Object Matching between Different Data Source

3.1 Checking Data Info

Data	#Voxels
bld1-54	241,613,693 in total and 4,646,418 per building
tree	59,640,000
dtmbot	641,624,355
be	17,460,029
blockhouse	3,392,202
dalton	1,887,512
quadrangle	3,161,733
roundhouse	6,037,174
scithe	1,231,821
Ifcid is not null	33,170,471
Total	976,048,519

3.2 Assign Temporary classID for IFC buildings

In table "voxel" and "voxelpt", GIS data occupied 944,110,209 rows.

At this moment, we assume the 6 IFC models with classID 57, 58, 59, 60, 61, and 62, respectively.

1. $\copy voxel(x, y, z, ifcID) FROM 'C:\Users\z5039792\Documents\Vox3DMod\data\bim\BE\$ classmodel.xyz' DELIMITER ' '; 2. UPDATE voxel SET classID=57 WHERE classid IS NULL; 3. $\COPY\ voxel(x, y, z, ifcID)\ FROM\ 'C:\Users\z5039792\Documents\Vox3DMod\data\bim\Bloom Bloom Bl$ ckHouse\classmodel.xyz' DELIMITER ' '; 4. UPDATE voxel SET classID=58 WHERE classid IS NULL; $\label{lem:copy_voxel} \begin{cal}{ll} 5. & COPY & voxel(x, y, z, ifcID) & FROM & C:\Users\z5039792\Documents\Vox3DMod\data\bim\Dal\ & Copy & Copy$ ton\classmodel.xyz' DELIMITER ' ' 6. UPDATE voxel SET classID=59 WHERE classid IS NULL; 7. \COPY voxel(x, y, z, ifcID) FROM 'C:\Users\z5039792\Documents\Vox3DMod\data\bim\Quadrangle\classmodel.xyz' DELIMITER ' '; 8. UPDATE voxel SET classID=60 WHERE classid IS NULL; 9. $\color{COPY voxel(x, y, z, ifcID) FROM 'C:\Users\z5039792\Documents\vox3DMod\data\bim\Rou}$ ndhouse\classmodel.xyz' DELIMITER ' '; 10. Figure 4. Log info for IFC data importing

3.3 Update classID for IFC buildings

For BE building, through computing bld19 and its the MAX & MIN (x,y) range in EPSG:28356 CRS, it is easy to find that they are in high probability the same building.

```
    SELECT MAX(x)*0.1+336300 AS maxx, MIN(x)*0.1+336300 AS minx, MAX(y)*0.1+6245507 AS maxy, MIN(y)*0.1+6245507 AS miny
    FROM voxel
    WHERE classid=57;
    SELECT MAX(x)*0.2+336000 AS maxX, MIN(x)*0.2+336000 AS minX, MAX(y)*0.2+6245250 AS maxY, MIN(y)*0.2+6245250 AS minY
    FROM voxel
    WHERE classID=19;
```

4	maxx numeric △	minx numeric △	maxy numeric △	miny numeric
1	336450.8	336301.6	6245552.9	6245508.6
1	336384.8	336300.8	6245552.4	6245519.4

Figure 5. (x,y) range for BE in EPSG:28356 CRS

Then, visualizing above two buildings in CloudCompare, it looks similar, at least in shape.

Figure 6. BE building in CloudCompare

Figure 7. bld19 in CloudCompare

For Blockhouse, Dalton, Quadrangle, Roundhouse, SciThe buildings, calculating (x,y) range for all buildings with classID<=54. And then retrieve same range for above 5 buildings to do matching.

```
    SELECT MAX(x)*0.1+336042 AS maxx, MIN(x)*0.1+336042 AS minx, MAX(y)*0.1+6245613 AS maxy, MIN(y)*0.1+6245613 AS miny
    FROM voxel
    WHERE classid=58;
    SELECT MAX(x)*0.1+336305 AS maxx, MIN(x)*0.1+336305 AS minx, MAX(y)*0.1+6245569 AS maxy, MIN(y)*0.1+6245569 AS miny
    FROM voxel
    WHERE classid=59;
    SELECT MAX(x)*0.1+336409 AS maxx, MIN(x)*0.1+336409 AS minx, MAX(y)*0.1+6245580 AS maxy, MIN(y)*0.1+6245580 AS miny
    FROM voxel
    WHERE classid=60;
    WHERE classid=60;
```

```
13. SELECT MAX(x)*0.1+336047 AS maxx, MIN(x)*0.1+336047 AS minx, MAX(y)*0.1+6245651 AS maxy, MIN(y)*0.1+6245651 AS miny

14. FROM voxel

15. WHERE classid=61;

16.

17. SELECT MAX(x)*0.1+336325 AS maxx, MIN(x)*0.1+336325 AS minx, MAX(y)*0.1+6245582 AS maxy, MIN(y)*0.1+6245582 AS miny

18. FROM voxel

19. WHERE classid=62;

20.

21. SELECT MAX(x)*0.2+336000 AS maxX, MIN(x)*0.2+336000 AS minX, MAX(y)*0.2+6245250 AS maxY, MIN(y)*0.2+6245250 AS minY

22. FROM voxel

23. WHERE classID<

44. GROUP BY classID;
```

Figure 8. (x,y) range for all 52 building

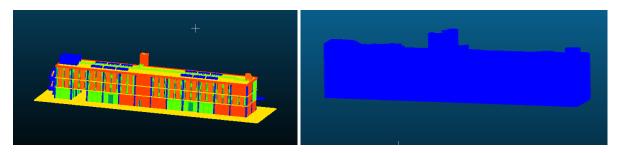

Figure 9. Blockhouse

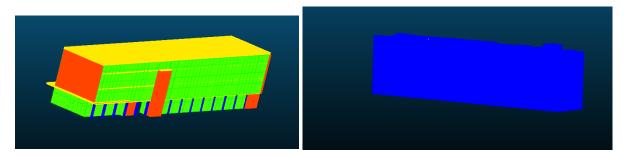

Figure 10. Dalton

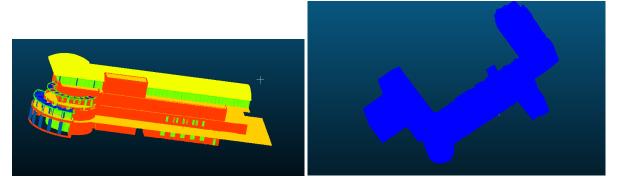

Figure 11. Quadrangle

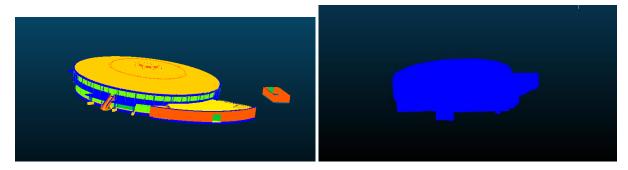

Figure 12. Roundhouse

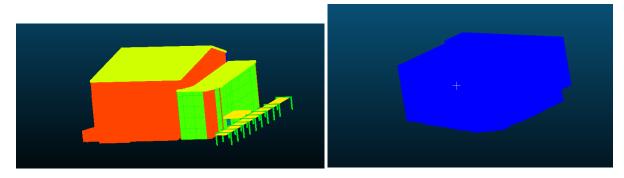

Figure 13. Science Theatre

In summary, the corresponding bld are list in below table:

Id	Name	Num	Old classID	New classID
Bld19	Built Environment	H13	57	19
Bld6	Blockhouse	G6	58	6
Bld9	Dalton	F12	59	9
Bld13	Quadrangle	E15	60	13
Bld44	Roundhouse	E6	61	44
Bld8	Science Theatre	F13	62	8

Update the 6 buildings:

```
1. UPDATE voxel SET classID=19 WHERE classid=57;
2. UPDATE voxel SET classID=6 WHERE classid=58;
3. UPDATE voxel SET classID=9 WHERE classid=59;
4. UPDATE voxel SET classID=13 WHERE classid=60;
5. UPDATE voxel SET classID=44 WHERE classid=61;
6. UPDATE voxel SET classID=8 WHERE classid=62;

Time: 1h 12m 19s
```

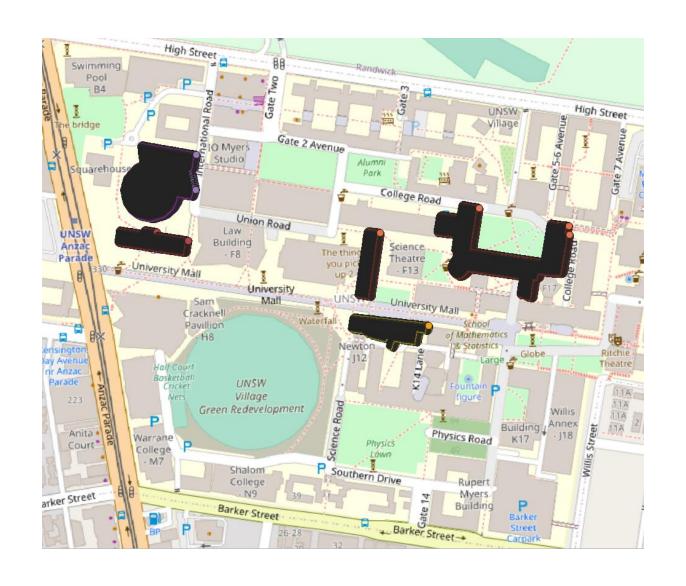

3.4 Assign Name for Each Building in Lower Campus

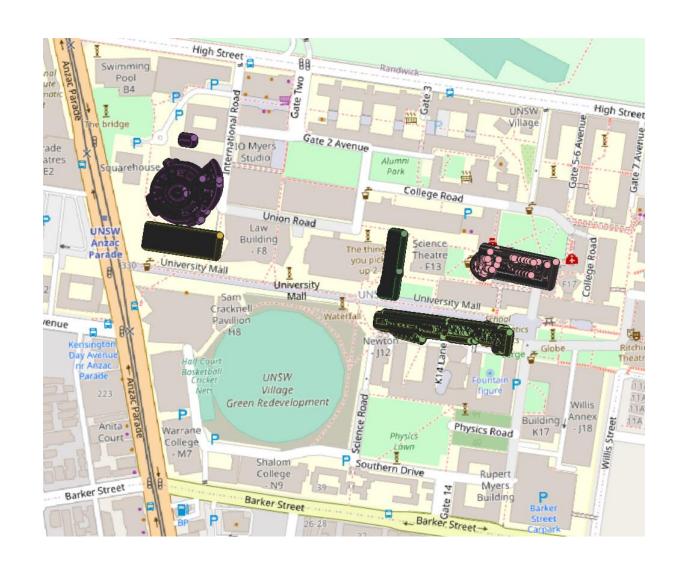

Ignore ...

4. Create Flat ARRAY Table

First of all we consider the simplest data layout – flat table for voxel data.

It is easy to regard each (x,y,z) coordinate along with its semantic information as one record in database table. To avoid further complex geometry translation and scaling operation for end user, we choose sacrifice storage space for the convenience of spatial queries. The data type for "x", "y" and "z" column will be set to "NUMERIC(8,1)" due to the precision of coordinates will not beyond 8.

4.1 Create Table

```
    DROP TABLE IF EXISTS voxelflat CASCADE;

   2. CREATE TABLE voxelflat
   3. (
   4.
           id serial PRIMARY KEY,
           x NUMERIC(8,1) NOT NULL,
   5.
   6.
           y NUMERIC(8,1) NOT NULL,
           z NUMERIC(8,1) NOT NULL,
   7.
           classID INTEGER,
   8.
           ifcID INTEGER
   10.);
Query returned successfully in 290 msec.
```

4.2 Import Data

We directly recalculate the coordinates (x,y,z) from the data in table "voxel". Due to the scale and offset compositions contain seven pairs, the vast majority of voxels is in 20cm and (336000,6245250,20) offset. In contrast, the other six pairs belong to special voxel with IFC feature. We need to separate to handle them one by one.

```
    INSERT INTO voxelflat(x,y,z,classID,ifcID)

    2. SELECT x*0.2+336000, y*0.2+6245250, z*0.2+20, classID, ifcID FROM voxel
   3. WHERE ifcID IS NULL;4. INSERT INTO voxelflat(x,y,z,classID,ifcID)
    5. SELECT x*0.1+336300, y*0.1+6245507, z*0.1+25, classID, ifcID FROM voxel
    6. WHERE classID=19 AND ifcID IS NOT NULL;

    INSERT INTO voxelflat(x,y,z,classID,ifcID)

    8. SELECT x*0.1+336042, y*0.1+6245613, z*0.1+27, classID, ifcID FROM voxel
    9. WHERE classID=6 AND ifcID IS NOT NULL;
    10. INSERT INTO voxelflat(x,y,z,classID,ifcID)
    11. SELECT x*0.1+336305, y*0.1+6245569, z*0.1+29, classID, ifcID FROM voxel
    12. WHERE classID=9 AND ifcID IS NOT NULL;
    13. INSERT INTO voxelflat(x,y,z,classID,ifcID)
    14. SELECT x*0.1+336409, y*0.1+6245580, z*0.1+31, classID, ifcID FROM voxel
    15. WHERE classID=13 AND ifcID IS NOT NULL;
    16. INSERT INTO voxelflat(x,y,z,classID,ifcID)
   17. SELECT x*0.1+336047, y*0.1+6245651, z*0.1+25, classID, ifcID FROM voxel 18. WHERE classID=44 AND ifcID IS NOT NULL;
    19. INSERT INTO voxelflat(x,y,z,classID,ifcID)
    20. SELECT x*0.1+336325, y*0.1+6245582, z*0.1+28, classID, ifcID FROM voxel
   21. WHERE classID=8 AND ifcID IS NOT NULL;
Query returned successfully in 2 h 30 min 50 secs.
```

After finishing filling in the voxel data in table "voxelflat", we next go to replace old "voxel" with "voxelflat".

```
1. DROP TABLE voxel;
2. ALTER TABLE voxelflat RENAME TO voxel;
```

4.3 Build Index

In order to speed up the queries involving spatial or semantic retrievals, we build default B-tree indices on "x", "y", "z", and two semantic columns "classID" and "ifcID".

```
1. DROP INDEX IF EXISTS idx_voxel CASCADE;
2. CREATE INDEX idx_voxel ON voxel(x, y, z, classID, ifcID);

Query returned successfully in 1 h 27 min 31 secs.
```

4	id Integer	x numeric (8,1)	y numeric (8,1)	z numeric (8,1)	classid Integer	ifcid Integer
1	571255464	336434.0	6245891.4	31.6	56	[null]
2	571255465	336434.0	6245891.4	31.8	56	[null]
3	571255466	336434.0	6245891.6	20.2	56	
4	571255467	336434.0	6245891.6	20.4	56	
5	571255468	336434.0	6245891.6	20.6	56	[null]

Figure . Example of flat ARRAY table.

5. Conversion to POINT geometry

In this section, we consider the second data layout, which stores each voxel as a geometry POINT including (x,y,z) by using PostGIS Geometry Constructors – "ST_MakePoint".

Spatial indices are one of the greatest assets of PostGIS. Here we use the generic index structure (GIST) for geometry column, and continue use B-tree index for other two semantic columns. While you can create a b-tree index on a geometry object (point, region, etc) it can only actually be used for equality as ordering comparisons like > are generally meaningless for such objects. A GiST index is required to support more complex and general comparisons like "contains", "intersects", etc. In a nutshell: B-Tree indexes perform better, but GiST indexes are more flexible.

https://postgis.net/docs/using_postgis_dbmanagement.html#idm2461

5.1 Create Table

```
1. CREATE EXTENSION IF NOT EXISTS POSTGIS;
2. DROP TABLE IF EXISTS voxelpt CASCADE;
3. CREATE TABLE voxelpt
4. (
5. id serial PRIMARY KEY,
6. classID INTEGER,
7. ifcID INTEGER,
8. geom geometry(POINTZ, 28356)
9. );

Query returned successfully in 4 secs 592 msec.
```

5.2 Import Data

```
INSERT INTO voxelpt(classID, ifcID, geom) SELECT classID, ifcID, ST_SetSRID (ST_MakePoin
t(x,y,z), 28356) FROM voxel AS VALUES;
Query returned successfully in 2 h 21 min 52 secs.
```

5.3 Build Index

```
1. DROP INDEX IF EXISTS idx_voxelpt CASCADE;
2. DROP INDEX IF EXISTS geom_ voxelpt CASCADE;
3. CREATE INDEX idx_voxelpt ON voxelpt(classID, ifcID);
4. CREATE INDEX geom_voxelpt ON voxelpt USING GIST (geom);

Query returned successfully in 6 h 33 min 18 secs.
```

Figure Example for POINT geometry table

6. Conversion to MULTIPOINT geometry

To enable the use of geometrical functions from PostGIS, POINTs are transformed into MULTIPOINT type, which is a collection of POINTs.

6.1 Create table

```
1. DROP TABLE IF EXISTS voxelmpt CASCADE;
2. CREATE TABLE voxelmpt
3. (
4. id serial PRIMARY KEY,
5. classID INTEGER,
6. ifcID INTEGER,
7. geom geometry(MULTIPOINTZ, 28356)
8. );

Query returned successfully in 272 msec.
```

6.2 Partition Principles

- Rule-1: For general building objects without IFC features, each building is one Multipoint.
- Rule-2: For building objects with IFC objects, we regard each IFC object as one Multipoint.
- Rule-3: For tree and dtmbot, we combine GIS dataset to decide the patch size.

6.3 Data Generation

6.3.1 Building without IFC

First, for general building voxels without IFC semantic information, we straightforward collect all POINTs in "voxelpt" with same classID into one MULTIPOINT geometry. We have tried to generate multipoint geometry including each building, but due to geometry size limit

```
1. DO $$
   2. DECLARE
   3.
          f record;
   4. BEGIN
           FOR idx in 1..54
   6.
         L00P
               IF idx = 26 OR idx = 46 THEN
   7.
                  raise notice 'The buidling % could not be found', idx;
   8.
   9.
   10.
                  INSERT INTO voxelmpt(classID, geom)
                   VALUES (idx, ST_Collect(ARRAY(SELECT geom FROM voxelpt WHERE ifcID IS
   11.
       NULL AND classID=idx)));
   12. END IF;
   13.
           END LOOP;
   14. END;
   15. $$
   16.
Query returned successfully in 119 min 40 secs.
```

6.3.2 Building with IFC

Next, for building objects with IFC features, each partition is a collection of IFC voxels with same ifcID.

```
1. DO $$
   2. DECLARE
           f record;
   3.
   4. BEGIN
   5.
           FOR f in SELECT DISTINCT classID, ifcID
               FROM voxelpt
   6.
   7.
               INSERT INTO voxelmpt(classID, ifcID, geom)
   8.
   9.
               VALUES (f.classID, f.ifcID, ST Collect(ARRAY(SELECT geom FROM voxelpt WHE
       RE ifcID IS NOT NULL AND classID=f.classID AND ifcID=f.ifcID)));
   10.
           END LOOP;
   11. END;
   12. $$
   13.
Query returned successfully in 9 min 31 secs.
```

6.3.3 Tree

Last, for tree, there is another tree data set. It consists of points, which represent the trunk of the tree. So using this point as a center (total 1345 POINTs) and assuming an horizontal radius (3-4m) we can try to partition the trees. Note that, above strategy may be not suitable to our tree voxels since the interception range of Voxel data and GIS data is different, and the location is offset.

```
    pg_dump -U postgres -h 149.171.16.253 -p 5432 -t tree crc_lcl_proj | psql - h 149.171.16.253 -p 5433 -U postgres -d voxeldb
    pg_dump -U postgres -h 149.171.16.253 -p 5432 -t terrain crc_lcl_proj | psql - h 149.171.16.253 -p 5433 -U postgres -d voxeldb
```

A straightforward method is calculating the buffer of each GIS tree point with radius=4m via PostGIS function "ST_Buffer" (https://postgis.net/docs/ST_Buffer.html). Assign tree voxels an ifcID=30 and name='tree'.

```
    INSERT INTO ifcclass(ifcid, name) VALUES (30, 'tree');

   2. DO $$
   3. BEGIN
   4. FOR idx in 1..1345
   5.
           LOOP
               INSERT INTO voxelmpt(classID, ifcID, geom)
   6.
   7.
                VALUES (54, 30, ST_Collect(ARRAY(
                   SELECT V.geom
   8.
   9.
                    FROM voxelpt V
                   JOIN tree T ON ST_WITHIN(V.geom, ST_Buffer(T.geom, 4, 'quad_segs=8'))
   10.
   11
                   WHERE V.classid=54 AND T.id=idx)));
   12.
           END LOOP;
   13. END;
   14. $$
Query returned successfully in 14 min 17 secs.
```

6.3.4 Dtmbot

Actually, we have to create terrain objects with respect to the surface objects as paths, gardens, roads. Jinjin has these vector non-overlapping polygons. You can use them to find 'all voxels of the dtm in a specific polygon' and assign the semantic of the polygon. Then the dtm will be not partitioned randomly but according to the surface objects.

```
    pg_dump -U postgres -h 149.171.16.253 -p 5432 -t lawn crc_lcl_proj | psql -h 149.171.16.253 -p 5433 -U postgres -d voxeldb
    pg_dump -U postgres -h 149.171.16.253 -p 5432 -t road crc_lcl_proj | psql -h 149.171.16.253 -p 5433 -U postgres -d voxeldb
    pg_dump -U postgres -h 149.171.16.253 -p 5432 -t building crc_lcl_proj | psql -h 149.171.16.253 -p 5433 -U postgres -d voxeldb
```

For Windows OS, backup the table "lawn" and "road" through PgAdmin with "plain" and "UTF8" in .sql file. After that, restoring these two tables through psql command:

```
    \i C:/Users/z5039792/Documents/Vox3DMod/data/lawn.sql
    \i C:/Users/z5039792/Documents/Vox3DMod/data/road.sql
    \i C:/Users/z5039792/Documents/Vox3DMod/data/building.sql
```

We consider the following objects on the terrain that will become the partition rules.

- Road
- Greenarea
- Building

6.3.4.1 Road Surface

For "road", there are 118 polygons, we aim to group dtmbot voxels into such 118 polygons. Here, we can utilize function "ST_WITHIN" (https://postgis.net/docs/ST_Within.html) to decide which set of voxelx are located in which polygon. Besides, we need to allocate one semantic label for this kind of "road" object. Due to few knowledge of road in UNSW campus (only FME id), we decide to assign "road" semantic as a near IFC semantic, that is, we temporarily set up 27 as ifcID value for "road" object.

```
    INSERT INTO ifcclass(ifcid, name) VALUES (27, 'road');

    2. DO $$
    3. BEGIN
    4.
            FOR idx in 1..118
    5.
            LO<sub>OP</sub>
                INSERT INTO voxelmpt(classID, ifcID, geom)
    6.
                VALUES (55, 27, ST_Collect(ARRAY(
    7.
    8.
                    SELECT V.geom
    9.
                    FROM voxelpt V
                    JOIN road R ON ST_WITHIN(V.geom, R.geom)
    10.
    11.
                    WHERE V.classid=55 AND R.id=idx)));
    12.
            END LOOP;
    13. END;
   14. $$
Query returned successfully in 145 min 16 secs.
```

6.3.4.2 Greenarea Surface

For "greenarea", there are 120 polygons, we aim to group dtmbot voxels into such 120 polygons. Same as "road", we decide to assign "greenarea" semantic as a near IFC semantic, that is, we temporarily set up 28 as ifcID value for "greenarea" object.

```
1. INSERT INTO ifcclass(ifcid, name) VALUES (28, 'greenarea');
2. DO $$
3. BEGIN
4. FOR idx in 1..120
5. LOOP
6. INSERT INTO voxelmpt(classID, ifcID, geom)
7. VALUES (55, 28, ST_Collect(ARRAY(
8. SELECT V.geom
```

```
9. FROM voxelpt V
10. JOIN greenareas G ON ST_WITHIN(V.geom, G.geom)
11. WHERE V.classid=55 AND G.gid=idx)));
12. END LOOP;
13. END;
14. $$
15.
```

6.3.4.3 Building Surface

For "building", there are 121 polygons, we aim to group dtmbot voxels into such 121 polygons. Different from "road" and "greenarea", we have already had multiple source building semantic information (e.g., point cloud, BIM). It is better to set up the corresponding ID. The challenge is we have no idea about point cloud building (such as name).

One option is to build a hierarchical data model for the whole voxel dataset. Following links are for reference:

- https://coderwall.com/p/whf3-a/hierarchical-data-in-postgres
- https://www.cybertec-postgresql.com/en/postgresql-speeding-up-recursive-queries-and-hierarchic-data/
- https://www.pinnsg.com/modeling-hierarchical-data-postgres/

Another option is we ignore semantic information and only consider how to store terrain slice according to the footprint of the building. Thus, giving all terrain belong to building surface a same ifcid = 29 ("building").

```
    INSERT INTO ifcclass(ifcid, name) VALUES (29, 'building');

   2. DO $$
   3. BEGIN
           FOR idx in 1..121
   4.
   5.
               INSERT INTO voxelmpt(classID, ifcID, geom)
   6.
               VALUES (55, 29, ST_Collect(ARRAY(
   7.
   8.
                   SELECT V.geom
   9
                   FROM voxelpt V
                   JOIN building B ON ST WITHIN(V.geom, B.geom)
   10.
                   WHERE V.classid=55 AND B.id=idx)));
   11.
           END LOOP;
   12.
   13. END;
Query returned successfully in 119 min 18 secs.
```

Don't forget to update the "ifcID" for building voxels without IFC semantic.

```
UPDATE voxelmpt SET ifcID=29 WHERE classid=ifcID IS NULL;

Query returned successfully in 107 msec.
```

6.3.4.4 Others

For other dtmbot voxels, we can directly ignore them due to no semantic information.

6.4 Summary

4	id integer	classid integer	ifcid integer	st_astext text

pa PCPATCH(1)
```

);

7.2 Partition Principles

Same as MULTIPOINT partition:

- Rule-1: For general building objects without IFC features, each building is one Multipoint.
- Rule-2: For building objects with IFC objects, we regard each IFC object as one Multipoint.
- Rule-3: For tree and dtmbot, we combine GIS dataset to decide the patch size.

7.3 Data Generation

7.3.1 Building without IFC

```
1. DO $$
    2. BEGIN
           FOR idx in 1..54

8. Align the IFC with the Extrusion Buildings

The alignment can be according to the footprint from the 2D map. In general, the orientation of the footprint should be correct, but the shape and size might differ.

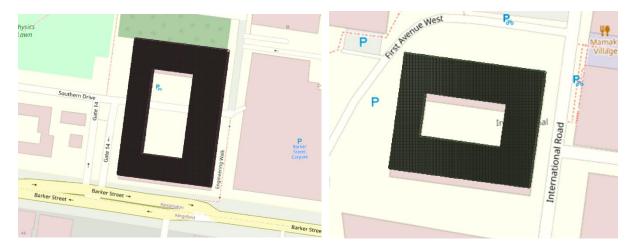

What has been given as one footprint on the 2D map might have been two buildings and vice versa... two footprints have been drawn for one building. This might happen with buildings like Red Centre (check OSM map: https://www.openstreetmap.org/#map=19/-33.91822/151.22950). What is on the maps in not wrong: the footprint represents the outline of the building that 'steps' on the terrain. If there is a tunnel or a sky bridge or an overhanging part ... they are not represented on the map. Therefore when we have extruded building (as all these 50+ buildings with flat roofs), some discrepancies in the shape may occur.

I suggest you measure the offset in QGIS with respect to the footprint of the map. What I will do I would print all extruded buildings in groups of 5-10 to see how well they fit with the foot prints. They are obtained from the footprints, so they have to be the same. If they are not the same I will created a MMBB of three buildings far from each other, e.g. in the corners of the area we are working on. Then I will get three points with x, y coordinates and compare with the same x,y coordinates from the 2D map. From these points I will compute affine transformation and determine shift and rotation. This shoft and rotation I will apply to the whole extruded buildings.

Then I will print each IFC building and compare with the footprint of the 2D map. This will be not straightforward because the footprint will not fit that well with the IFC building (print). So you have to visually decide which point to use for the shift and translation (no scaling should be applied).

7.1 Point cloud

Check "bld1" and "bld2" in OGIS:

"bld3" cannot be visualized in QGIS because of memory allocation problem.

Check "bld4" and "bld5" in QGIS:

Offset: 336000, 6245250, 20

X*0.1+offset

First, we consider modifying offset only and keep each (x,y) unchanged.

Case-I: Only move y

y-5

• y-3, 100*0.1+**6245250** = y coordinate=**6245251-3=6245247**

• <u>v-2</u>

Case-II: Only move x

Case-III: Move x and y

==> 336000, 6245247, 20

After "y" correction:

New problem comes up: Part of voxel in one object may be redundant. For instance, in "bld4", some voxels are on the road. So the next step is to select all the buildings of this kind of problem.

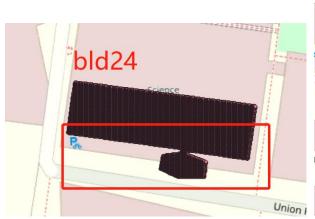

Buildings with redundant voxels:

- bld4
- bld10 contains two buildings (K17 and J17)

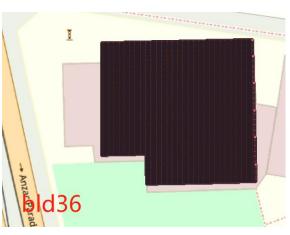

When visualizing "bld10", new problem has arisen. That is, only changing offset is not enough, we need to change (x,y) for each voxel in bld10. Besides, some of them are redundant, some of them are missing. We can drop the redundant part, but how to fill in the missing pieces. And do we need to separate this into two buildings or keep that?

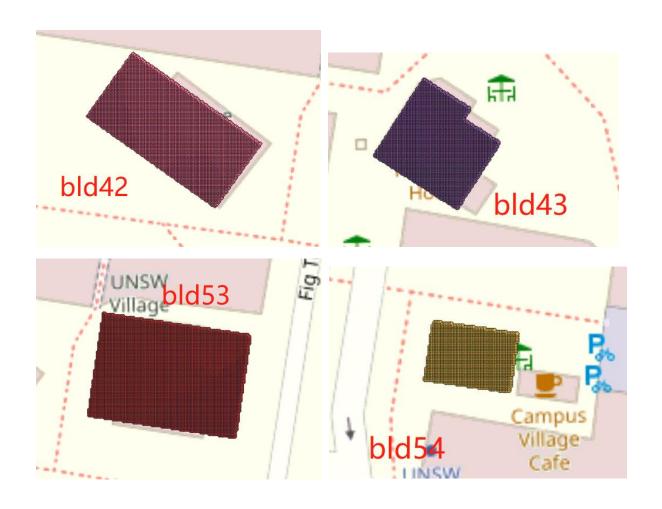

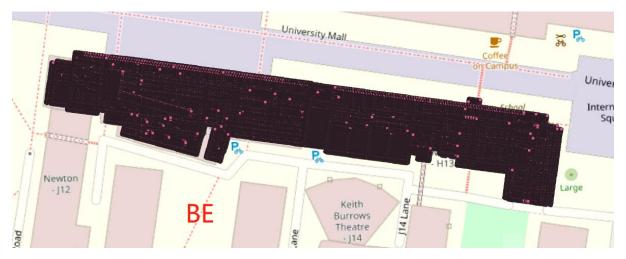

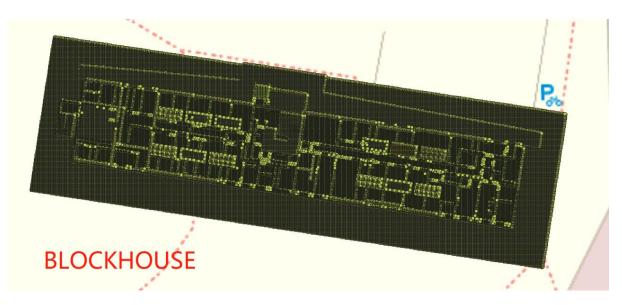

7.2 IFC

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336300, 6245507, 25) as geom from voxelmpt where classid=19 and ifcid is not null;

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336042, 6245613, 27) as geom from voxelmpt where classid=6 and ifcid is not null;

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336305, 6245569, 29) as geom from voxelmpt where classid=9 and ifcid is not null;

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336409, 6245580, 31) as geom from voxelmpt where classid=13 and ifcid is not null;

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336047, 6245651, 25) as geom from voxelmpt where classid=44 and ifcid is not null;

select ST_Translate(ST_Scale(geom, 0.1,0.1,0.1), 336325, 6245582, 28) as geom from voxelmpt where classid=8 and ifcid is not null;

9. Sample Queries and QGIS Visualization

The data query is processed using a HP laptop. Its processor is Intel(R) Core (TM) i7-7600 CPU @ 2.80GHz and its installed memory is 16.0 GB. Its operating system is 64-bit Windows 10. And the test is performed on PostgreSQL (11.2), PostGIS (2.5.2), and QGIS (3.6.1).

2.1 Sample Visualization

Considering bld52 (we don't have building name at this moment), 29.6MB and 1,881,847 voxels, we extract "geom" first, and then convert its coordinate into EPSG:28356.

Figure 3 shows how to execute query in QGIS.

Figure 3. Query execution in QGIS

Note that, loading the above query result as a new layer in QGIS may take several minutes and 3D view is as well. Once choosing 3D view, please keep an eye out for your GPU and memory changes, if you crash, kill the task or stop doing the work at hand and continue to wait patiently. If not necessary or you are not confident in your PC, don't try 3D view.

Figure 3. 2D and 3D visualization of "bld52" in QGIS
